

Classes next week

Tue	09.11		No class
Wed	10.11	12.15	Nooruse 1 – 121
Thu	11.11	12.15	Ostwaldi 1 – B103

STUDING HUMAN EVOLUTION THROUGH GENETICS

Evolution and the Natural World

Lecture 18

04/11/2021

Vasili Pankratov

Questions in human evolution

BAD Questions in human evolution

- Who was the first ancestor of humans?
- When/where did humans originate?

Non-genetic Questions in human evolution

- What was the fitness advantage of bipedalism?
- When/where/how/by whom were the first stone tools produced?
- In what environment did a particular group of hominins live? What kind of social structure did they have?

Genetic Questions in human evolution

- What is the ancestry of modern humans?
 - Genetic relationships between different human populations
 - Migrations – spread of humans across the globe
 - Changes in population size
 - Genetic interactions with other hominin groups

Genetic Questions in human evolution

- What genetic changes happened during human evolution?
 - Genetic differences from other species/groups (chimp, Neandertal) and between groups
 - What genetic loci (regions in the genome) did natural act upon at different times and in different populations

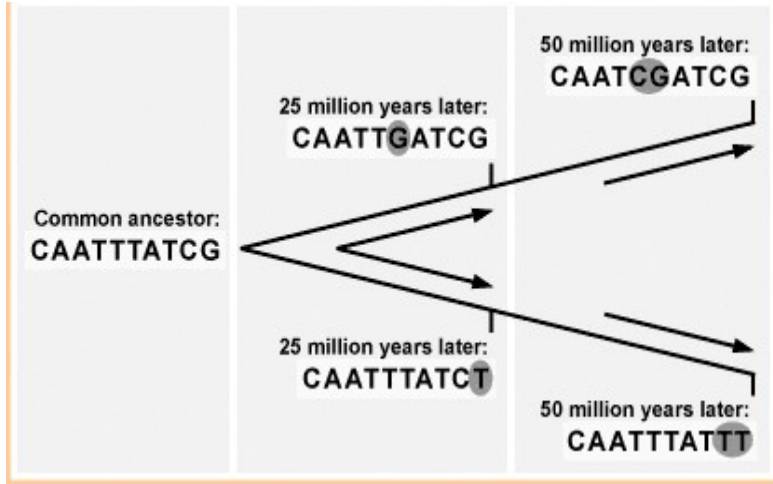

Genetic data we use

<https://eu.idtdna.com/pages/education/decoded/article/genotyping-terms-to-know>

- DNA source:
 - Modern humans
 - Ancient samples (bones, teeth, mummies etc.)
- DNA analysis:
 - Whole genome sequencing
 - Genotyping a set of known genetic polymorphisms
 - Analyzing only Y-chromosome or mtDNA

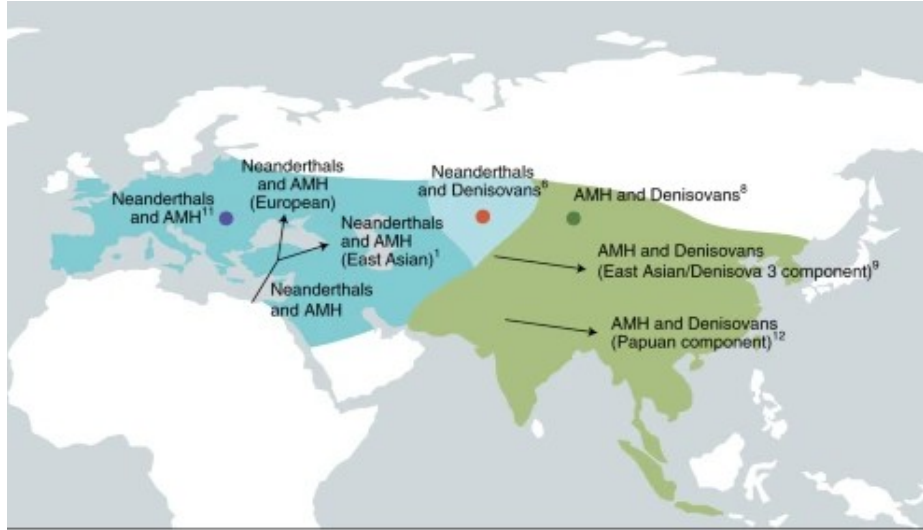

What to do with the DNA sequences?

- Measure similarity between individuals and genetic diversity within a group of people
- Cluster (group) individuals based on genetic similarities
- Compare to DNA of other species
- Build phylogenetic trees
- Date tMRCA of sequences (molecular clock)
- Reconstruct the number of ancestors
- Predict molecular effects of mutations

DECIPHERING HUMANS DEMOGRAPHIC PAST

Main questions:

- How did modern humans spread across the globe?
- How did they genetically interact with other hominins (specifically Neandertals and Denisovans)

https://www.nature.com/articles/s41559-018-0729-6?WT.feed_name=subjects_genetics

Mitochondrial DNA

- Small – cheap to sequence
- Maternally inherited
- Haploid – only one “version” of the sequence in a given individual
- Non-recombining – evolution can be represented with a tree; relatively easy to analyze
- A very small part of the genome – not telling the complete story
- The story with Y-chromosome is quite similar

Mitochondrial DNA of modern humans

Mitochondrial DNA: archaics

Mitochondrial DNA: conclusions

- Non-African haplogroups are nested within African ones – suggests an out-of-Africa migration
- TMRCA of non-African haplogroups around 40-70 kya
- Native American haplogroups are nested within East Asian ones – peopling of America from Asia
- TMRCA of all humans around 100-200 kya (mitochondrial Eve)
- Evidence about relationships to Neandertal and Denisovan are conflicting

Nuclear (autosomal) DNA

- Huge – more expensive to sequence
- Inherited from both parents – as complete information as possible
- Diploid – distinguishing the two homologous chromosomes from each other when sequencing is challenging
- Affected by recombination – relatively harder to analyze but allows additional inference based on recombination
- Because of recombination it doesn't make sense to build phylogenetic trees of entire chromosomes
- But there are multiple other analysis we can do

Recombination

<https://smithplanet.com/stuff/gedmatch.htm>

- We might have ancestors that we didn't get any DNA from

Recombination

- Recombination provides a way to date events like admixture

Global genetic diversity

Human genomic diversity and percentage of Neanderthal plus Denisovan ancestry in modern humans

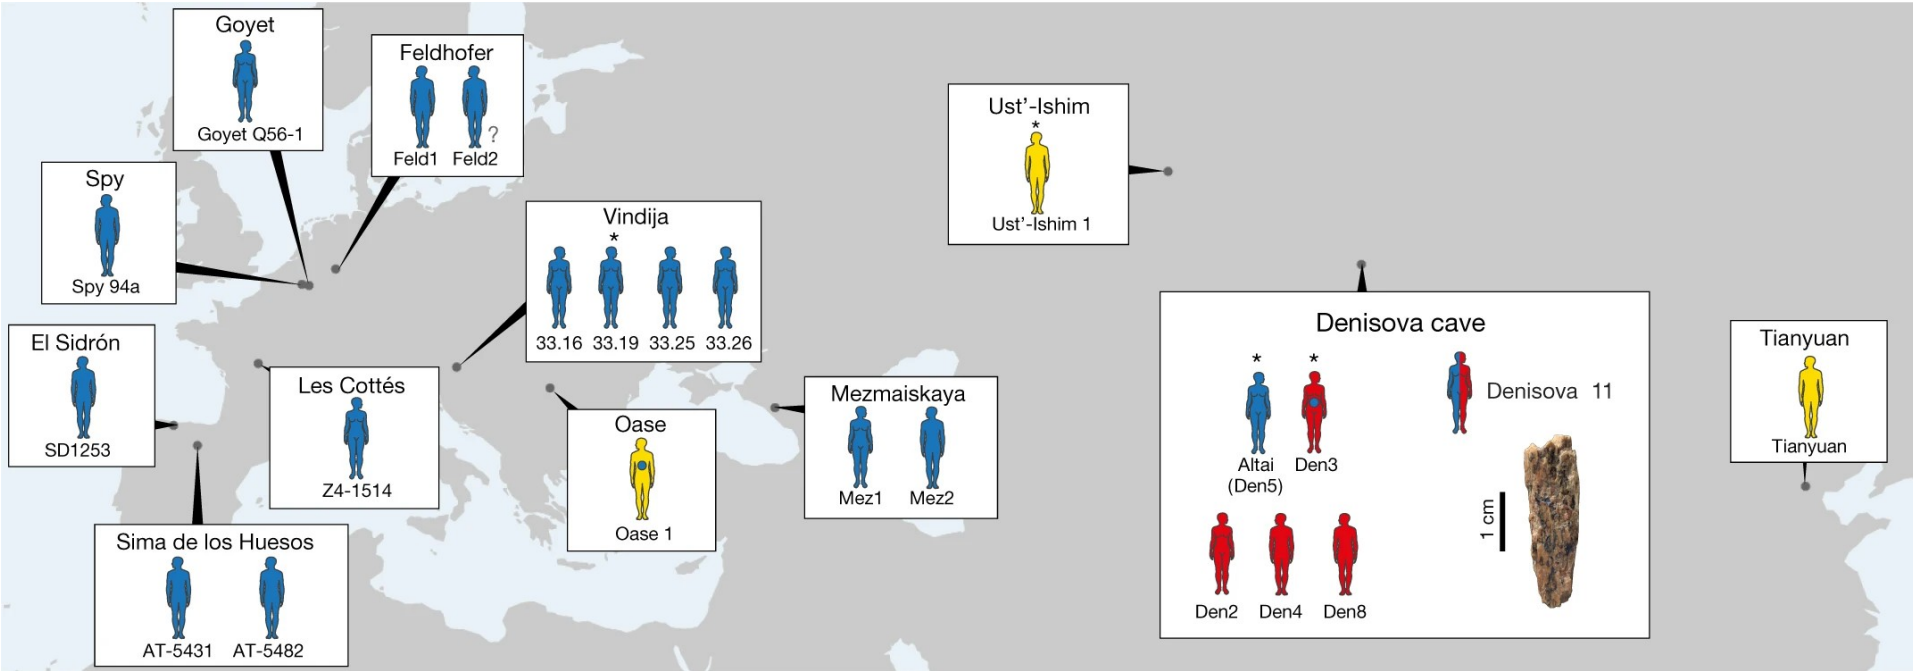

Land areas are resized based on mean genomic heterozygosity

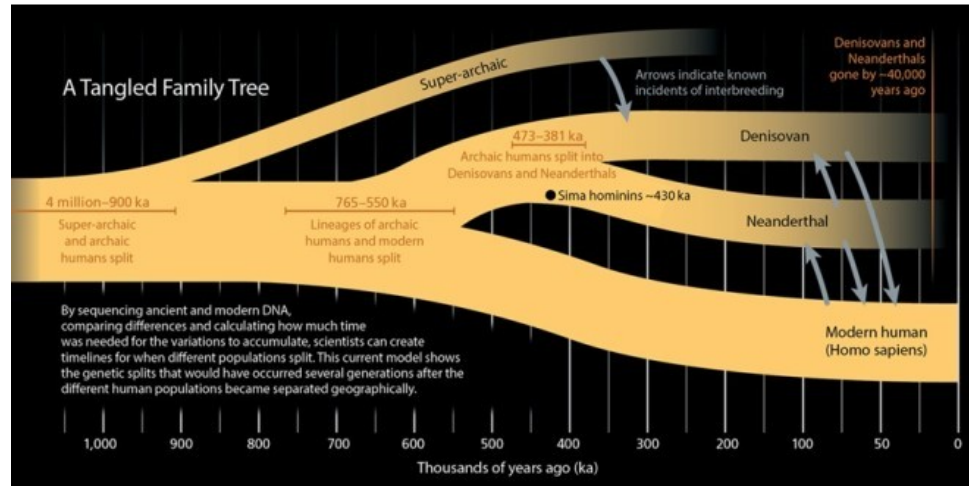

Interpolated surface of percentage of Neanderthal plus Denisovan ancestry in modern humans

- Higher genetic diversity in Africa – evidence of out-of-Africa bottleneck
- Humans out of Africa have ~2% of their DNA coming from Neanderthals
- Humans in Asia and especially Papua have some DNA from Denisovans

Interactions with Neandertals

Conclusions

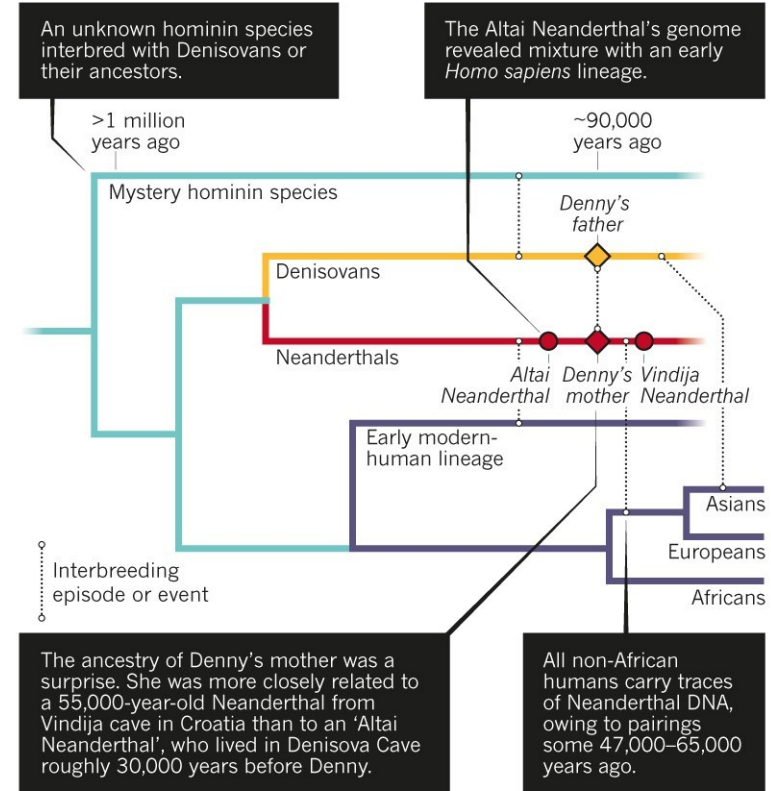

<https://www.discovermagazine.com/the-sciences/meet-the-denisovans>

<https://www.nature.com/articles/d41586-018-06004-0>

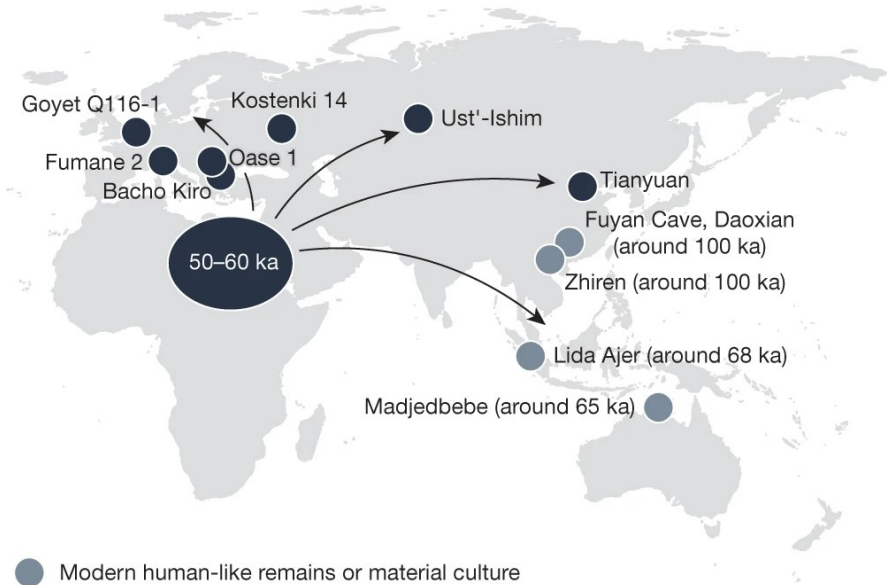

TANGLED TREE

A female born to a Neanderthal mother and Denisovan father roughly 90,000 years ago — nicknamed Denny — is one of many examples of interbreeding between ancient human groups.

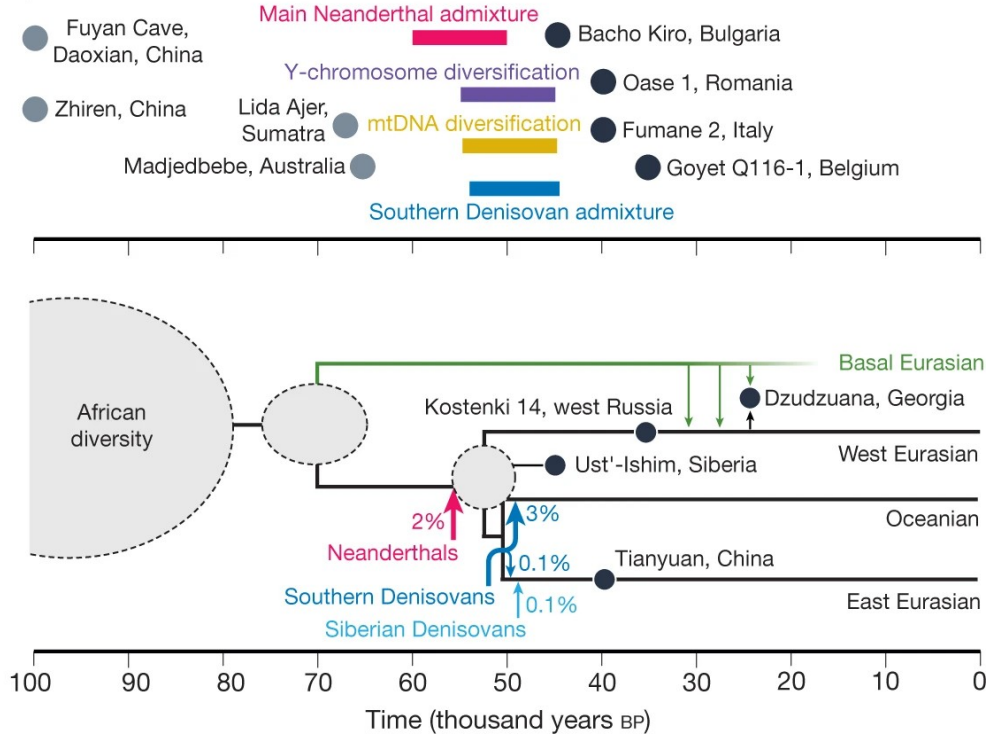

Conclusions

a

b

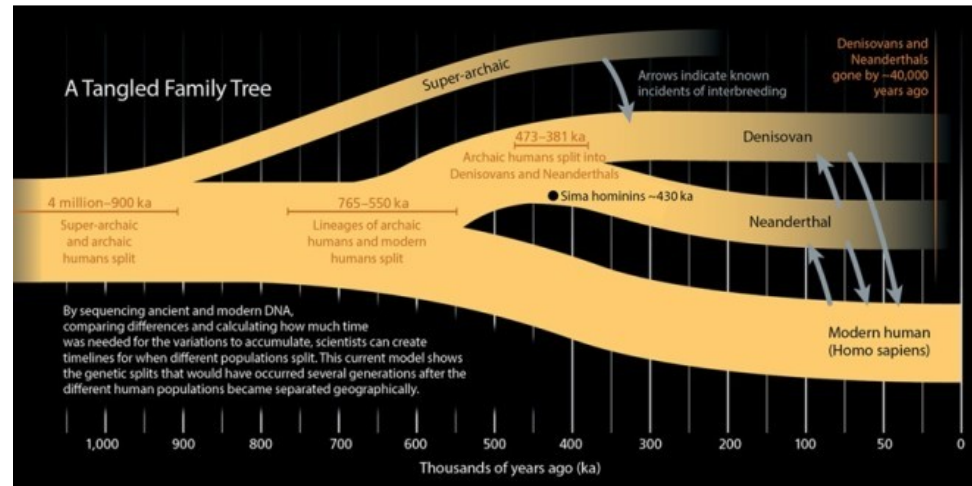

Conclusions

- The ancestry of modern-day non-Africans can be mostly traced to Africa if we go further back in time than 50-60 kya
- The out-of-Africa migration was associated with a bottleneck resulting in lower genetic diversity out of Africa
- Around 2% of the genomes of non-Africans can be attributed to admixture with Neandertals that happened around 55 kya somewhere in West Asia
- Denisovans also contributed to some populations of modern humans
- Generally, there was a lot of interbreeding between different hominins
- There was a lot happening in Africa in terms of migration and admixture but we generally know less about it

Challenge questions

- There are fossils of anatomically modern humans outside Africa older than 60 kya. How can we match this with the genetic data?
- What is the problem with the tree below and how to explain it?

HOW GENETICALLY
DIVERSE ARE HUMANS
NOWADAYS?

Genetic similarity and geography

<https://genomeinquirer.org/2020/05/19/i-study-population-genomics/>

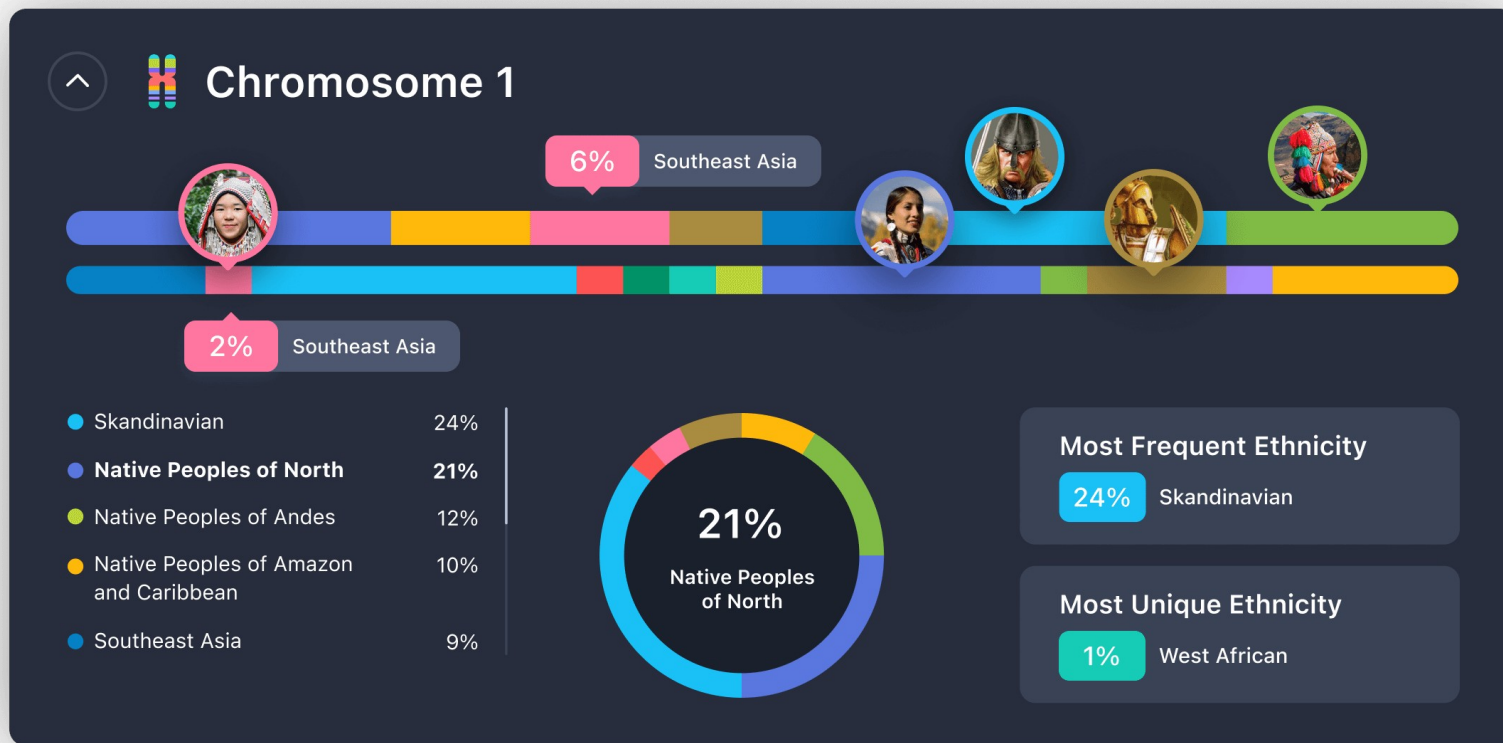

<https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4958967/>

Genetic similarity and geography

Commercial DNA testing

Conclusions

- On average, the closer the places of birth of 2 individuals are, the higher the genetic similarity between them
- We can trace genetic ancestry of an individual by comparing his/her DNA to a “reference panel”. Different parts of the genome might come from different ancestries
- Some of the genetic differences between humans are neutral but some have phenotypic effects
- Because of that results of genetic studies done on Europeans can't be easily extrapolated on other human populations
- Understanding how human genetic diversity was shaped is important for medical genetics

GENETIC CHANGES AND PHENOTYPIC EVOLUTION

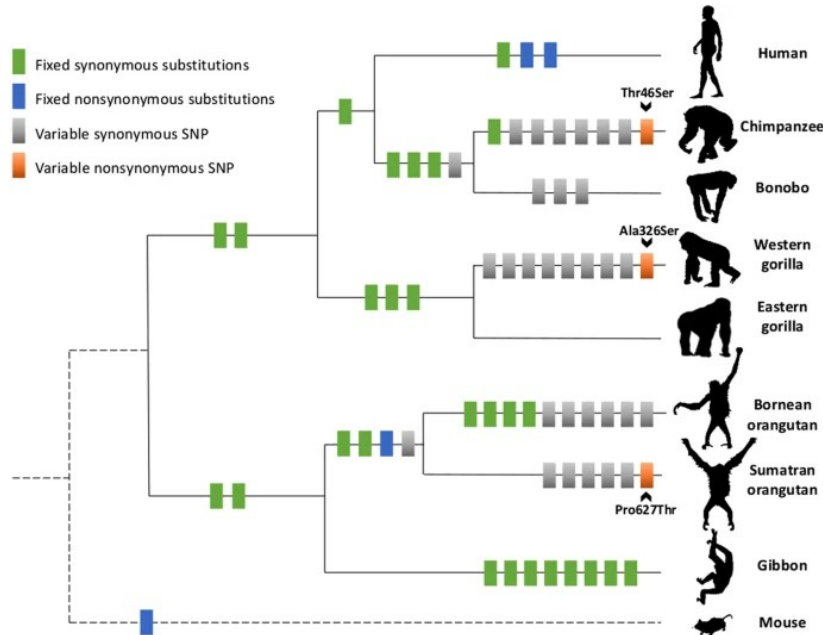

What mutations made us human?

<https://elifesciences.org/articles/63713>

- Find alleles fixed in humans and unique to humans
- However:
 - There are many such mutations (tens of thousands)
 - Mutations might get fixed due to genetic drift
 - Some selection events in early human evolution might be not related to “humanization”
 - In general, it is not easy to link a mutation to a phenotype

Some examples

<https://www.nature.com/articles/s41598-017-16844-x>

- FOXP2 – a gene involved in brain development; associated with severe speech impairment; has 2 nonsynonymous changes fixed in humans
- However
 - little evidence for action of selection
 - Neandertal and Denisovan have those substitutions as well

<https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6128738/>

Some examples

- A recent study found ~500 mutations fixed in humans and not present in other species incl. Neanderthal/Denisovans that likely cause changes in gene expression
- The potentially affected genes are expressed in vocal cords and voice box, as well as being associated with neurological and craniofacial phenotypes

Local (population-specific) adaptations

- One idea is to look for mutations that are young but have high frequency
- Examples of phenotypes/conditions
 - High altitude
 - Drinking milk
 - Diseases (malaria, sleeping sickness)
 - Light pigmentation (vitamin D synthesis)
 - Diving

Conclusions

- We can search for genomic loci that have experienced the action of positive natural selection in the past by using either modern or ancient DNA
- In some cases we might link a locus to a phenotype but in many cases we can't

Why does all this matter?

- Understanding genetic differences between humans help in medical genetic studies
- Mutations of Neandertal/Denisovan origin are more likely to have phenotypic effects
- Knowing the demographic history of humans / a specific population may help to build neutral expectation for many analysis
- Loci that experienced natural selection in the past are functionally relevant
